Temperature in Farhenite:  131.0
```

Practical 1:

Write a program that accepts the mass of an object (in kilograms) and its velocity (in meters per second), then calculates and displays the momentum of the object. The momentum p is calculated using the formula:p=m XU where: m is the mass of the object (in kilograms). v is the velocity of the object (in meters per second).

Input Format: A single floating-point number representing the mass of the object in kilograms. A single floating-point number representing the velocity of the object in meters per second. Output Format: The output will display calculated momentum with appropriate units (kgm/s) (rounded up to 2 decimal places).

```python
"""momentum"""
m = float(input("enter mass (in kg)  :"))
v = float(input("enter velocity(in m/s) : "))
momentum = m*v
print(f"momentum = {momentum:.2f} kgm/s")
```

```
ython learning\Strings\string.py'
50795' '--' 'c:\x5cUsers\x5cACER\x5cDesktop\x5cpython learning\x5cStrings\x5cstring.py' enter mass (in kg)  :2.5
enter velocity(in m/s) : 44.5
momentum = 111.25 kgm/s
```
